## Understanding Direct Variation

Direct variation describes a relationship between two variables in which one variable is a constant multiple of the other. Mathematically, this relationship is expressed as  $y = kx$ , where  $k$  is the constant of proportionality. If one variable increases, the other increases at a consistent rate, maintaining their ratio. Recognizing direct variation is fundamental in algebra and forms the basis for understanding linear functions. This concept is also widely applicable in fields such as physics, where certain quantities vary directly with others, like distance and time at constant speed.

## The Mathematical Definition

In a direct variation, the equation  $y = kx$  represents the relationship between variables  $x$  and  $y$ , with  $k$  being a nonzero constant. The value of  $k$

determines how steeply  $y$  increases as  $x$  grows. For example, if  $k = 3$ , then  $y$  triples for every unit increase in  $x$ . This simple linear equation is foundational for solving more complex algebraic problems.

## Graphical Representation

Graphs of direct variation equations are straight lines passing through the origin  $(0,0)$ . This characteristic is crucial because it visually confirms the proportional relationship. The slope of the line equals the constant  $k$ , indicating the rate at which  $y$  changes relative to  $x$ . Understanding this graphical aspect helps students interpret data and functions more effectively.

## **Sample Direct Variation Problems and Solutions**

Below are examples of typical problems found in a direct variation worksheet with answers, illustrating how to apply the concept effectively.

1.

**Problem:** If  $y$  varies directly with  $x$  and  $y = 12$  when  $x = 4$ , find the constant of variation and write the equation.

**Answer:** Since  $y = kx$ , substitute  $y = 12$  and  $x = 4$ :

$$12 = k * 4 \rightarrow k = 12 / 4 = 3.$$

Equation:  $y = 3x$ .

2.

**Problem:** Given  $y = 5x$ , find  $y$  when  $x = 7$ .

**Answer:** Substitute  $x = 7$  into  $y = 5x$ :

$$y = 5 * 7 = 35.$$

3.

**Problem:** Determine if  $y$  varies directly with  $x$  if  $y = 2x + 3$ .

**Answer:** No, because  $y = 2x + 3$  does not pass through the origin. The presence of  $+3$  indicates it is not a direct variation.

4.

**Problem:** A car travels 60 miles in 2 hours. Assuming direct variation between distance and time, how far will it travel in 5 hours?

**Answer:** Let  $d = kt$ . Use given values:

$$60 = k * 2 \rightarrow k = 30.$$

For 5 hours:  $d = 30 * 5 = 150$  miles.
